

```
fun append (xs,ys) =  
  if xs=[]  
  then ys  
  else (hd xs)::append(tl xs,ys)  
  
fun map (f,xs) =  
  case xs of  
    [] => []  
  | x::xs' => (f x)::(map(f,xs'))  
  
val a = map (increment, [4,8,12,16])  
val b = map (hd, [[8,6],[7,5],[3,0,9]])
```

Anonymous Functions

Toward anonymous functions

- Definitions unnecessarily at top-level are still poor style:

```
fun triple x = 3*x
fun triple_n_times (f,x) = n_times(triple,n,x)
```

- So this is better (but not the best):

```
fun triple_n_times (f,x) =
  let fun trip y = 3*y
  in
    n_times(trip,n,x)
  end
```

- And this is even smaller scope
 - It makes sense but looks weird (poor style; see next slide)

```
fun triple_n_times (f,x) =
  n_times(let fun trip y = 3*y in trip end, n, x)
```

Anonymous functions

- This does not work: A function *binding* is not an *expression*

```
fun triple_n_times (f,x) =  
  n_times((fun trip y = 3*y) , n, x)
```

- This is the best way we were building up to: an expression form for *anonymous functions*

```
fun triple_n_times (f,x) =  
  n_times((fn y => 3*y) , n, x)
```

- Like all expression forms, can appear anywhere
- Syntax:
 - **fn** not **fun**
 - **=>** not **=**
 - no function name, just an argument pattern

Using anonymous functions

- Most common use: Argument to a higher-order function
 - Don't need a name just to pass a function
- But: Cannot use an anonymous function for a recursive function
 - Because there is no name for making recursive calls
 - If not for recursion, **fun** bindings would be syntactic sugar for **val** bindings and anonymous functions

```
fun triple x = 3*x  
val triple = fn y => 3*y
```
