```
fun append (xs,ys) =
    if xs=[]
    then ys
    else (hd xs)::append(tl xs,ys)

fun map (f,xs) =
    case xs of
      [] => []
      | x::xs' => (f x)::(map(f,xs'))

val a = map (increment, [4,8,12,16])
val b = map (hd, [[8,6],[7,5],[3,0,9]])
```

Programming Languages Dan Grossman

ML Type Inference

Overview

- Will describe ML type inference via several examples
 - General algorithm is a slightly more advanced topic
 - Supporting nested functions also a bit more advanced
- Enough to help you "do type inference in your head"
 - And appreciate it is not magic

Key steps

- Determine types of bindings in order
 - (Except for mutual recursion)
 - So you cannot use later bindings: will not type-check
- For each val or fun binding:
 - Analyze definition for all necessary facts (constraints)
 - Example: If see x > 0, then x must have type int
 - Type error if no way for all facts to hold (over-constrained)
- Afterward, use type variables (e.g., 'a) for any unconstrained types
 - Example: An unused argument can have any type
- (Finally, enforce the *value restriction*, discussed later)

Very simple example

Next segments will go much more step-by-step

Like the automated algorithm does

```
val x = 42 (* val x : int *)

fun f (y, z, w) =
    if y (* y must be bool *)
    then z + x (* z must be int *)
    else 0 (* both branches have same type *)

(* f must return an int
    f must take a bool * int * ANYTHING
    so val f : bool * int * 'a -> int
    *)
```

Relation to Polymorphism

- Central feature of ML type inference: it can infer types with type variables
 - Great for code reuse and understanding functions
- But remember there are two orthogonal concepts
 - Languages can have type inference without type variables
 - Languages can have type variables without type inference
