```
fun append (xs,ys) =
    if xs=[]
    then ys
    else (hd xs)::append(tl xs,ys)

fun map (f,xs) =
    case xs of
        [] => []
      | x::xs' => (f x)::(map(f,xs'))

val a = map (increment, [4,8,12,16])
val b = map (hd, [[8,6],[7,5],[3,0,9]])
```

A Module Example

A larger example [mostly see the code]

Now consider a module that defines an Abstract Data Type (ADT)

  – A type of data and operations on it

Our example: rational numbers supporting **add** and **toString**

```
structure Rational1 =
struct
datatype rational = Whole of int | Frac of int*int
exception BadFrac

(*internal functions gcd and reduce not on slide*)

fun make_frac (x,y) = …
fun add (r1,r2) = …
fun toString r = …
end
```

Library spec and invariants

Properties [externally visible guarantees, up to library writer]

– Disallow denominators of 0

– Return strings in reduced form ("4" not "4/1", "3/2" not "9/6")

– No infinite loops or exceptions

Invariants [part of the implementation, not the module's spec]

– All denominators are greater than 0

– All `rational` values returned from functions are reduced

More on invariants

Our code maintains the invariants and relies on them

Maintain:
- **make_frac** disallows 0 denominator, removes negative denominator, and reduces result
- **add** assumes invariants on inputs, calls **reduce** if needed

Rely:
- **gcd** does not work with negative arguments, but no denominator can be negative
- **add** uses math properties to avoid calling **reduce**
- **toString** assumes its argument is already reduced
